

How much of each apparent association is shared silence rather than shared design?

Diverging scale centred at zero because this difference, unlike V itself, can take either sign. Red = the pair looks more associated once silence counts as a design choice (documentation behaviour). Blue = silence dilutes a real association. Dots mark pairs that change conclusion (significance flip at BH $q < 0.05$ or $|\delta|$ above the flip threshold); they are listed in data/analysis/family_nr_flips.csv.
